A reference material designed for the determination of anthropogenic and natural radionuclides in sediment, IAEA-384 (Fangataufa Lagoon sediment), is described and the results of certification are presented. The material has been certified for 8 radionuclides: $^{90} 	ext{Sr}$, $^{137} 	ext{Cs}$, $^{210} 	ext{Po}$, $^{226} 	ext{Ra}$, $^{228} 	ext{Th}$, $^{232} 	ext{Th}$, $^{238} 	ext{U}$, $^{240} 	ext{Pu}$ and $^{248} 	ext{Pu}$). Information values are given for 12 radionuclides: $^{90} 	ext{Sr}$, $^{137} 	ext{Cs}$, $^{210} 	ext{Po}$, $^{226} 	ext{Ra}$, $^{228} 	ext{Th}$, $^{232} 	ext{Th}$, $^{234} 	ext{U}$, $^{235} 	ext{U}$, $^{238} 	ext{U}$, $^{240} 	ext{Pu}$ and $^{248} 	ext{Pu}$. The reference material may be used for quality management of radionuclide laboratories engaged in the analysis of radionuclides in the environment, as well as for the development and validation of analytical methods and for training purposes. The material is available from IAEA in 100 g units.
Introduction

The IAEA Marine Environment Laboratory (IAEA-MEL) in Monaco has conducted intercomparison exercises on radionuclides in marine samples for many years as part of its contribution to the IAEA's programme of Analytical Quality Control Services (AQCQ). An important part of the AQCQ programme has been a production of Reference Materials (RMs) and their provision to radioanalytical laboratories. The RMs have been developed for different marine matrices (sediment, water, biota), with accuracy and precision required for the present state of the art of radiochemistry and mass spectrometry methods.

The RMs have been produced as the final products of world-wide intercomparison exercises organized over the last 30 years. A total of 44 intercomparison exercises were undertaken and 39 RMs were produced for radionuclides in the marine environment. All required matrices (seawater, biota, sediment) were covered with radionuclide concentrations ranging from typical environmental levels to elevated levels affected by discharges from nuclear reprocessing plants.

Collection and preparation of large volume samples (over 100 kg) requires to use specific methods for their pre-treatment. The required long-term availability of RMs (over 10 years) also necessitates their long-term stability. The production of a RM is a long process, covering the identification of needs, sample collection, pre-treatment, homogenization, bottling, distribution to laboratories, evaluation of data, preliminary reporting, additional analyses in expert laboratories, certification of the material, and finally issuing the RM.

In this paper we describe the RM IAEA-384 Fangataufa Lagoon sediment designed for the determination of anthropogenic and natural radionuclides in marine environment. This RM has been prepared to provide laboratories the possibility of testing the performance of their analytical methods on a sediment sample with elevated radionuclide levels due to nuclear weapons tests. Participating laboratories were requested to determine as many radionuclides as possible by radiochemistry (alpha, beta and gamma-spectrometry) and mass spectrometry (ICPMS – inductively coupled plasma mass spectrometry, TIMS – thermal ionization mass spectrometry, AMS – accelerator mass spectrometry) methods.

Experimental

Description of the material

About 158 kg of sediment was collected by IAEA-MEL in July 1996 in Fangataufa Lagoon (French Polynesia), where nuclear weapons testing had been carried out. It was expected, therefore, that the sediment would contain elevated levels of radionuclides formed during nuclear weapons tests, such as 60Co, 90Sr, 137Cs, 155Eu, 239Pu, 239+240Pu, 241Pu and 241Am.

After box coring the sediment was frozen for 2 hours at -40 °C, then freeze-dried with a +5 °C increase in temperature per hour. Secondary drying was done over 24 hours under a 0.02 mbar pressure at a constant temperature of +40 °C. The sediment was then ground into powder, sieved at 250 μm, homogenized under nitrogen gas and bottled in flasks under nitrogen gas (100 g per bottle).

Particle size analysis showed about 58% of the sediment was below 63 μm and 84% below 125 μm. The composition of the sediment is almost 100% of CaCO3 and the density is (2.64±0.06) g cm⁻³. The moisture content of the sediment was determined by drying several aliquots in an oven at 80 °C to constant weight (1–2 days) and was found to be 1.3% at the time of sample preparation. It was recommended that the water content be checked prior to use and that all results be reported on a dry-weight (dw) basis.

Sample dispatch and data return

The sample aliquots were distributed to participating laboratories during 1997–1998. One hundred and ten laboratories worldwide agreed to participate. Each participant received 100 g of the sediment sample. For each radionuclide analyzed, the following information was requested: (1) average weight of sample used for analysis; (2) number of analyses; (3) massic activity (Bq kg⁻¹ dw) corrected for blank, background etc.; (4) estimation of the total uncertainty (counting and other uncertainties); (5) description of chemical procedure and counting equipment; (6) reference standard solutions used during analysis; and (7) chemical recoveries, counting time and decay corrections.

A total of 94 sets of results were received from participants and included in the evaluation report of the intercomparison exercise. High quality data from the intercomparison exercise and additional data received from expert laboratories were included in the certification process, results of which are reported in the present paper.
Data treatment

The massic activities of 15 anthropogenic and 21 natural radionuclides were reported. The statistical programmes used for data evaluation were the same as described in previous IAEA-MEL AQCS reports 6–8. Calculations were based on the assumption of non-parametric distribution of data to which distribution-free statistics are applicable. When not provided by the laboratory, means were calculated from individual results either as arithmetic means with corresponding uncertainties when more than two results were reported, or as weighted means with weighted uncertainties in the case of only two results reported. The values below the detection limits were segregated from the results and the remaining values were checked for the presence of outliers using the box and whisker plot test. Medians were calculated from the results passing the test, rounded off to the most significant figure of the uncertainty. These values were considered to be the most reliable estimates of the true values. Confidence intervals were determined from a non-parametric sample population and were expressed as two-sided intervals representing 95% confidence limits.

Following the IUPAC10 and ISO11 recommendations for assessment of laboratory performance, the Z-score methodology was used in the evaluation of results. The Z-score was calculated according to:

\[ Z = (x_i - x_a)/s_b \]

where \( x_i \) is the robust mean of the massic activity values reported by laboratory \( i \), \( x_a \) is the assigned value (mean value of accepted results), and \( s_b \) is the target standard deviation.

The selection of the right target value depends on the objectives of the exercise. For radionuclide analysis, laboratories were required to have a relative bias below 20% (\( s_b < 10\% \)). The uncertainty of the assigned value (\( s_m \)) was included in the target value for bias by:12

\[ Z = (x_i - x_a)/s_b' = s_i^2 + s_m^2 \]

The performance of laboratories in terms of accuracy was expressed by the Z-scores for each radionuclide. The performance was considered to be acceptable if the difference between the robust mean of the laboratory and the assigned value (in \( s_b \) units) was less than or equal to two. A Z-score from 2 to 3 indicates that the results are of questionable quality. If \( |Z| > 3 \), the analysis was considered to be out of control.

The Z-score distributions were symmetric (after excluding outliers) and usually with Z-scores below 2, indicating that the performance of the laboratories was satisfactory. A typical example of the Z-score analysis for \(^{60}\text{Co} \) is shown in Fig 1. The Z-score evaluation represents a simple method which gives participating laboratories a normalized performance score for bias.

![Z-score distribution for \(^{60}\text{Co} \) in IAEA-384](image)
Criteria for certification

The certification process was carried out following the ISO Guide 35 using the most precise data from the intercomparison exercise and additional data from expert laboratories. For data sets comprising 5 or more accepted laboratory means, median values and confidence intervals were calculated as estimations of true massic activities. The median was considered as the certified value when: (1) at least 5 laboratory means were available, calculated from at least 3 different laboratories, and (2) the relative uncertainty of the median did not exceed ±5% for activities higher than 100 Bq kg⁻¹ dw, ±10% for activities from 1 to 100 Bq kg⁻¹ dw and ±20% for activities lower than 1 Bq kg⁻¹ dw.

An activity value was considered as an information value when at least 5 laboratory means of the same order of magnitude calculated from the results of at least 2 different laboratories were available.

Results and discussion

Homogeneity tests

The homogeneity of the sample was checked by measuring the activity of ⁶⁰Co, ¹³⁷Cs, ¹⁵⁵Eu, ²¹⁰Po, ²²⁶Ra, ²³⁹+²⁴⁰Pu and ²⁴¹Am on 30 bottles taken at random. Gamma-spectrometric measurements obtained by non-destructive gamma-spectrometry were performed in 10 to 220 g samples, ²³⁹Pu, ²³⁹+²⁴⁰Pu and ²⁴¹Am were determined by alpha-spectrometry on 0.1 to 5 g samples. Homogeneity was determined using one-way analysis of variance. The coefficient of variation was below 10% for both gamma- and alpha-spectrometrically determined radionuclides. The "between samples" variances showed no significant differences from the "within sample" variances for all radionuclides tested. Thus, the material was considered to be homogeneous for the tested radionuclides at the weight ranges used.

Anthropogenic radionuclides with certified activities

Participant results of 10 anthropogenic radionuclides (⁶⁰Co, ¹³⁷Cs, ¹⁵⁵Eu, ²³⁸Pu, ²³⁹Pu, ²⁴⁰Pu, ²³⁹+²⁴⁰Pu, ²⁴¹Pu and ²⁴¹Am) in Fangataufa Lagoon sediment were evaluated: 5 radionuclides (⁶⁰Co, ¹⁵⁵Eu, ²³⁸Pu, ²³⁹+²⁴⁰Pu and ²⁴¹Am, Table 1) were certified, and information values were given for 5 radionuclides (⁹⁰Sr, ¹³⁷Cs, ²³⁹Pu, ²⁴⁰Pu, ²⁴¹Pu, Table 2).

As an example, Figs 2 to 4 present the evaluation results in order of ascending massic activities for ⁶⁰Co, ²³⁹+²⁴⁰Pu and ²⁴¹Am. Also shown are the distribution medians and corresponding confidence intervals.

₆⁰⁰Co Data representing 45 laboratory means were used in the certification process (Fig 2). Gamma-spectrometry was used in all analyses. The data show very good homogeneity, falling less than the standard deviations from the distribution mean. The Z-score values were below 2.2, showing reasonable performances by the laboratories (Fig 1). The median given as the certified value is 2.50 Bq kg⁻¹ dw (95% confidence interval is (2.40–2.60) Bq kg⁻¹ dw).

¹⁵⁵Eu 30 laboratory means were used in the certification process. Gamma-spectrometry was used in all analyses. The data set was homogeneous, within two standard deviations of the distribution mean. The Z-score values were below 2.0, showing good performances by the laboratories. The median given as the certified value is 7.0 Bq kg⁻¹ dw (95% confidence interval is (6.7–7.3) Bq kg⁻¹ dw).

387
Plutonium isotopes

The majority of participants used conventional radiochemical methods based on sample treatment, ion-exchange separation followed by electrodeposition and alpha-spectrometry. Some laboratories combined ion-exchange separation with liquid-liquid extraction, or used only the liquid-liquid extraction. Resins (a single TRU column or double UTEVA + TRU columns) for the separation and subsequent electrodeposition for alpha-spectrometry (\(^{239}\text{Pu}\)) and/or for direct ICPMS and AMS analysis (\(^{239}\text{Pu}, \ ^{240}\text{Pu}, \ ^{241}\text{Pu}, \ ^{242}\text{Pu}\)) were also used. The samples for mass spectrometry analyses were either leached from stainless steel discs after alpha-spectrometry measurements, or analyzed directly in mass spectrometers. Generally, a reasonable agreement was obtained between alpha-spectrometry and mass spectrometry results, although the latter were mostly found on the right side of the distribution mean.

\(^{239}\text{Pu}\) 35 data sets obtained by alpha-spectrometry were evaluated. The data were homogeneous, within two standard deviations of the distribution mean. The Z-score values were below 2.2 showing reasonable performances by the laboratories. The median, given as the certified value, is 39.0 Bq kg\(^{-1}\) dw (95% confidence interval is (38.6–39.6) Bq kg\(^{-1}\) dw).

\(^{239+240}\text{Pu}\) 44 data sets obtained by alpha-spectrometry, ICPMS and AMS were included in the evaluation (Fig. 3). The data were homogeneous, within two standard deviations of the distribution mean. The Z-score values were below 2.1 showing reasonable performances by the laboratories. The median, given as the certified value is 107 Bq kg\(^{-1}\) dw (95% confidence interval is (103–110) Bq kg\(^{-1}\) dw).

\(^{241}\text{Am}\) 57 results (38 obtained by gamma-spectrometry and 19 by alpha-spectrometry) were available for statistical treatment (Fig 4). The data fell within less than 2 standard deviations from the distribution mean. Generally, the results obtained by gamma-spectrometry were in agreement with alpha-spectrometry data. The combined Z-score values were below 2. The median, given as the certified value, is 7.1 Bq kg\(^{-1}\) dw (95% confidence interval is (6.7–7.4) Bq kg\(^{-1}\) dw).
Natural radionuclides with certified values

Analytical results for 10 natural radionuclides in Fangatauva Lagoon sediment were evaluated: 3 radionuclides were certified $^{40}$K, $^{239}$Th and $^{238}$U, Table 1) and information values were estimated for 7 radionuclides $^{210}$Pb ($^{210}$Po), $^{226}$Ra, $^{232}$Ra, $^{232}$Th, $^{234}$U and $^{235}$U, Table 2) As an example, Fig. 5 presents the evaluation results with the corresponding standard deviations in order of ascending massic activity for $^{238}$U, as obtained by alpha-spectrometry, ICPMS and TIMS

$^{40}$K 25 laboratory means, all obtained by gamma-spectrometry were available for data evaluation Some of the laboratories encountered problems with calibration and the correct estimation of the background under the $^{40}$K photopeak The data showed reasonable homogeneity The Z-score values of accepted data were below 2.1, showing reasonable performances by the laboratories The median, given as the certified value, is 6.8 Bq kg$^{-1}$ dw (95% confidence interval is (6.5–7.1) Bq kg$^{-1}$ dw)

$^{230}$Th 10 reported laboratory means obtained by alpha-spectrometry were accepted in the evaluation The data set was homogeneous, within 2 standard deviations of the distribution mean The Z-score values were below 2.3 The median, given as the certified value, is 2.50 Bq kg$^{-1}$ dw (95% confidence interval is (2.38–2.61) Bq kg$^{-1}$ dw)

$^{238}$U 11 laboratory means obtained by gamma-spectrometry, 15 obtained by alpha-spectrometry, 2 by ICPMS and 1 by TIMS were used in the evaluation (Fig 5) As the precision and accuracy of gamma-spectrometry results were low, they were excluded from certification The Z-score values were below 1.8 The median of the combined alpha and mass spectrometry data (Fig 5) gives the certified value of 35.5 Bq kg$^{-1}$ dw (95% confidence interval is (33.4–36.8) Bq kg$^{-1}$ dw).
Anthropogenic radionuclides with information values

$^{90}$Sr. 15 laboratory means obtained by radiochemical treatment (mostly precipitation, $^{90}$Y extraction, and gas or scintillation counting) were available for the evaluation. The data show reasonable homogeneity, falling less than two standard deviations from the distribution mean. The Z-score values were below 1.7, showing good performances by the laboratories. The median, given as the information value, is 17 Bq kg$^{-1}$ dw (95% confidence interval is (15–19) Bq kg$^{-1}$ dw).

$^{137}$Cs. The evaluated data set based on 26 laboratory means obtained by gamma-spectrometry was homogenous within two standard deviations of the distribution mean. The Z-score values were below 2.2, showing reasonable performances by the laboratories. The median, given as the information value, is 0.30 Bq kg$^{-1}$ dw (95% confidence interval is (0.24–0.50) Bq kg$^{-1}$ dw).

$^{239}$Pu. 8 laboratory means (obtained by ICPMS and AMS) were available for data treatment (Fig 6), all results passed the outlier test. The Z-score values were below 1.7. The median, given as the information value is 98 Bq kg$^{-1}$ dw (95% confidence interval is (85–105) Bq kg$^{-1}$ dw).

$^{240}$Pu. 8 laboratory means were available for data treatment (Fig 6), all results passed the outlier test. The Z-score values were below 1.7. The median, given as the information value is 17.5 Bq kg$^{-1}$ dw (95% confidence interval is (15.1–18.7) Bq kg$^{-1}$ dw).

$^{241}$Pu. As $^{241}$Pu is a pure beta-emitter, mainly liquid scintillation spectrometry (LSS) was used for its determination (either directly on liquid samples, on discs, or from leached discs after alpha-spectrometry analysis). Alpha-spectrometry of the daughter $^{241}$Am, and ICPMS analyses were also used. Eight laboratory means were available for the evaluation, but as some of the ICPMS results were affected by analytical problems (e.g., contamination, calibration, etc.), they were not included in the calculation of the median. The Z-score values were below 1.5. The median given as the information value is 55 Bq kg$^{-1}$ dw (95% confidence interval is (41–69) Bq kg$^{-1}$ dw).
Natural radionuclides with information values

$^{210}$Pb and $^{210}$Po. 27 and 7 laboratory means were available for $^{210}$Pb and $^{210}$Po, respectively. Mostly gamma- and alpha-spectrometry (by $^{210}$Po ingrowth) were used for $^{210}$Pb, and alpha-spectrometry for $^{210}$Po. The Z-score values were below 1.7. Taking into account the time elapsed between collection and analysis of the sediment sample, we assumed that $^{210}$Pb and $^{210}$Po were in secular equilibrium. As the precision of alpha-spectrometry results was much better, the median was calculated from 13 laboratory means obtained by alpha-spectrometry only. The median given as the information value is 22 Bq kg$^{-1}$ dw (95% confidence interval is (21–23) Bq kg$^{-1}$ dw). Although the relative uncertainty for $^{210}$Pb ($^{210}$Po) is below 10%, these radioisotopes are listed in Table 2 with the information value only as two corrections should be applied during a storage time: (1) a correction for $^{210}$Pb decay (the half-life 22.3 y); and (2) a correction for in-growth of $^{210}$Pb from $^{226}$Ra.

$^{226}$Ra. 18 laboratory means obtained by gamma-spectrometry (including $^{214}$Bi measurements) were evaluated. The Z-score values were below 2. The median given as the information value is 2.4 Bq kg$^{-1}$ dw (95% confidence interval is (2.0–2.9) Bq kg$^{-1}$ dw).

$^{228}$Ra. 5 laboratory means obtained by gamma-spectrometry were evaluated. The median given as the information value is 16 Bq kg$^{-1}$ dw (95% confidence interval is (0.8–2.0) Bq kg$^{-1}$ dw).

$^{232}$Th. Alpha-spectrometry, gamma-spectrometry and mass spectrometry techniques were used in analyses. Only 3 laboratory means were accepted in the certification, 3 produced by alpha-spectrometry and 2 by ICPMS. The Z-score values were below 1.4, showing good performances by the laboratories. The median given as the information value is 0.022 Bq kg$^{-1}$ dw (95% confidence interval is (0.008–0.024) Bq kg$^{-1}$ dw).

$^{234}$U. 18 laboratory means were accepted for the evaluation. Total dissolution followed by alpha-spectrometry, with the exception of 3 results obtained by ICPMS, were used in the analysis. The Z-score values were below 1.8 showing good performances by the laboratories. The median, given as the certified value is 40 Bq kg$^{-1}$ dw (95% confidence interval is (35–43) Bq kg$^{-1}$ dw).

$^{235}$U. 17 gamma-spectrometry results, 11 alpha-spectrometry, 2 ICPMS and 1 TIMS results were used in the evaluation. The Z-score values were below 2. As the precision and accuracy of gamma-spectrometry measurements was low, the median was calculated using the alpha and mass spectrometry results only. The median given as the information value is 170 Bq kg$^{-1}$ dw (95% confidence interval is (160–190) Bq kg$^{-1}$ dw).

Less frequently reported radioisotopes

$^{228}$Th. The average massic activity from 4 laboratory means obtained by alpha- and gamma-spectrometry is (1.6±1.4) Bq kg$^{-1}$ dw.

$^{216}$Fr. One result obtained by AMS showed a massic activity of (84±7) $10^{-6}$ Bq kg$^{-1}$ dw.

$^{235}$Np. Three laboratory means obtained by alpha-spectrometry were evaluated. The average massic activity is (0.010±0.003) Bq kg$^{-1}$ dw.

$^{242}$Pu. One result obtained by ICPMS and one by AMS gave massic activities of (1.9±0.2) mBq kg$^{-1}$ dw and (0.7±0.3) mBq kg$^{-1}$ dw, respectively.
Isotopic ratios

$^{137}\text{Cs}/^{90}\text{Sr}$: The average $^{137}\text{Cs}/^{90}\text{Sr}$ activity ratio is 0.21±0.08, much lower than the global fallout value 1.5,17 due to the enhanced concentration of $^{90}\text{Sr}$ in the sediment of Fangataufa Lagoon.

$^{137}\text{Cs}/^{239+240}\text{Pu}$: The average $^{137}\text{Cs}/^{239+240}\text{Pu}$ activity ratio is 0.003±0.001, lower by 3 orders of magnitude than the global fallout ratio 17 due to the enhanced concentration of plutonium in the sediment.

$^{238}\text{Pu}/^{239+240}\text{Pu}$: The average $^{238}\text{Pu}/^{239+240}\text{Pu}$ activity ratio is 0.36±0.003, much higher than the global fallout value 0.025,17 confirming that most of the plutonium found in the lagoon is due to local fallout from nuclear weapons tests.

$^{241}\text{Pu}/^{239+240}\text{Pu}$: The average $^{241}\text{Pu}/^{239+240}\text{Pu}$ activity ratio is 0.52±0.06, much smaller than the global fallout value 15,18 due to the enhanced concentration of $^{239}\text{Pu}$ in the sediment.

$^{241}\text{Am}/^{239+240}\text{Pu}$: The average $^{241}\text{Am}/^{239+240}\text{Pu}$ activity ratio is 0.066±0.003, much smaller than the global fallout value 0.40,17 again due to the enhanced concentration of $^{239}\text{Pu}$ in the sediment.

$^{240}\text{Pu}/^{239}\text{Pu}$: The average $^{240}\text{Pu}/^{239}\text{Pu}$ activity ratio from 8 measurements made by ICPMS and AMS and 1 by high resolution alpha-spectrometry is 0.17±0.002, much lower than the global fallout ratio of 0.66.18 The average $^{240}\text{Pu}/^{239}\text{Pu}$ mass ratio is 0.049±0.001 (the global fallout ratio is 0.180)16 confirming that the origin of plutonium in Fangataufa Lagoon is due to local fallout from nuclear weapons tests.

Conclusions

The accurate and precise determinations of radionuclide concentrations in marine samples are essential for the assessments of the presence of radionuclides in the marine environment and their use in studies of oceanographic processes. To address the problem of data quality, and to assist IAEA Member States in verifying the performance of their laboratories, the IAEA-MEL has been developing RMs, which are important benchmark in quality management of laboratories.

Fangataufa Lagoon sediment sample (IAEA-384) was described in this paper and data on anthropogenic and natural radionuclides were evaluated. The medians of massic activities with 95% confidence intervals were chosen as the most reliable estimates of the true values IAEA-384 Fangataufa Lagoon sediment was certified as a RM for 8 radionuclides ($^{60}\text{Co}$, $^{90}\text{Sr}$, $^{137}\text{Cs}$, $^{226}\text{Ra}$, $^{228}\text{Ra}$, $^{228}\text{Th}$, $^{230}\text{Th}$, $^{232}\text{Th}$, $^{234}\text{U}$, $^{235}\text{U}$, $^{239}\text{Pu}$ and $^{241}\text{Am}$), and information values were estimated for 12 radionuclides ($^{60}\text{Co}$, $^{90}\text{Sr}$, $^{137}\text{Cs}$, $^{210}\text{Po}$, $^{226}\text{Ra}$, $^{228}\text{Ra}$, $^{228}\text{Th}$, $^{234}\text{U}$, $^{235}\text{U}$, $^{239}\text{Pu}$, $^{240}\text{Pu}$ and $^{241}\text{Pu}$). This RM may be used for quality management of radioanalytical laboratories, assessing the validity of radioanalytical methods and identifying weaknesses in methodologies, helping to detect training needs, and up-grading the quality of laboratories' performance.

The material is available from the IAEA in 100 g units.
