8<sup>th</sup> INPRO Dialogue  
Forum, Vienna, Austria

August 26-29, 2014

# Presentation Outline

---

- The current production version of G4ECONS
- Some proposed changes to G4ECONS
- Sample uncertainty analysis results in G4ECONS
- Implications from using uncertainty analysis

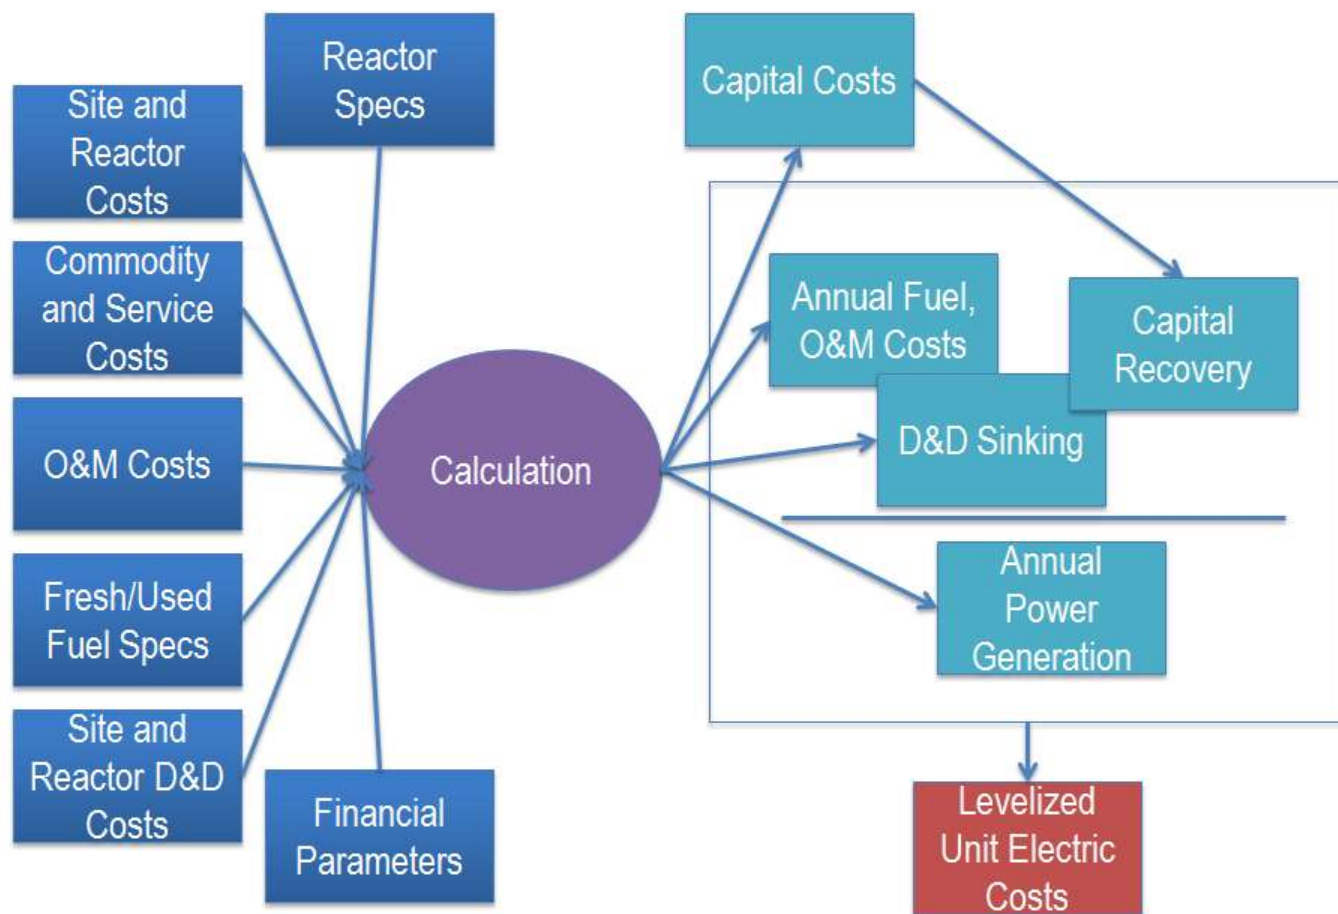

# Summary of the Presentation

---

- The current production version of G4ECONS is sufficient for levelised cost calculations
- Changes are being made to G4ECONS expand its applicability and utility to include uncertainty analysis
- Uncertainty quantification provides useful information, but care must be taken on how this is done

# The current production version of G4ECONS calculates a Levelised Unit Electric Cost (LUEC)

- Dark blue inputs
- Light blue calculations
- Red output

# The levelised cost is an important piece of information, but it is only one piece

---

- It gives the cost to generate electricity
- It does not provide a measure of the economic feasibility, that is, whether the nuclear project is a good investment
- As a point estimate, it does not describe the uncertainty associated with the cost to generate electricity

# The working revision to G4ECONS addresses these drawbacks

---

- Given an assumed price in an electricity market, a cash flow can be calculated
- Given an appropriate discount rate for that market's economy, a net present value (NPV) can be calculated from the cash flow
- Given a cost distribution for each component of cost, the overall uncertainty and component uncertainty can be calculated

# These expansions make G4ECONS a more useful planning tool

---

- Placing the economic analysis within the context of a market allows planners to gauge the effects of changing conditions
- Evaluating the NPV provides a measure of the attractiveness for investors and industrial partners
- Uncertainty analysis shows which components would benefit most from research and development or market support

# The LUEC calculation needs only a few technical input parameters

| Parameter          | Information     |
|--------------------|-----------------|
| Reactor Type       | PWR             |
| Thermal Power      | 3900 MWt        |
| Thermal Efficiency | 33.33%          |
| Power Density      | 38 MWt/MTU      |
| Capacity Factor    | 90%             |
| Fuel               | 3.78% LEU Oxide |
| Fuel Source        | Natural U       |
| Tails              | 0.21%           |
| Burnup             | 43.68 GWtd/MTU  |
| Lifetime           | 40 years        |
| Interest Rate      | 5%              |

All values based on System 80 data

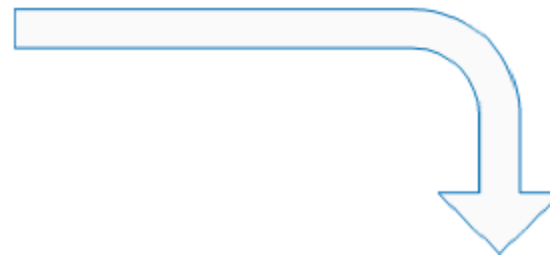

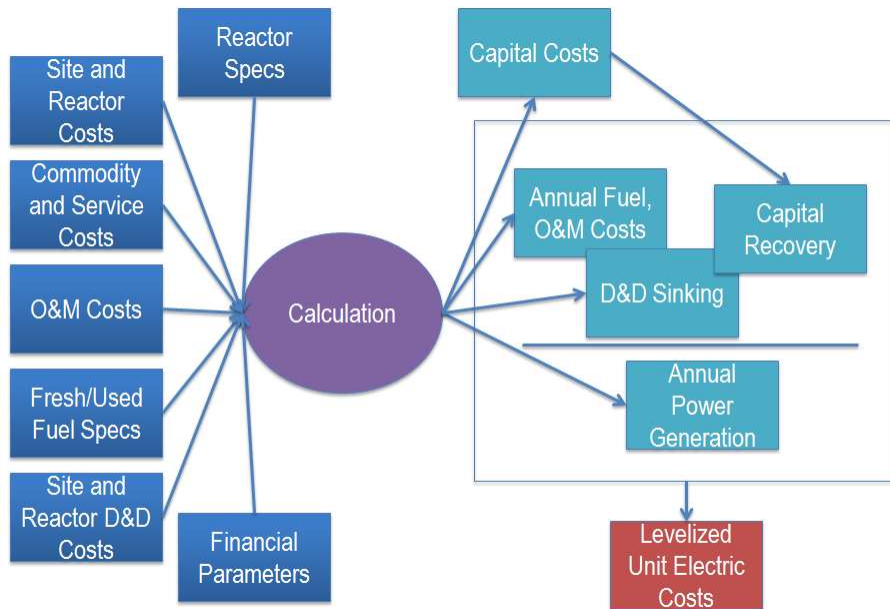

# Nominal cost numbers are based on US DOE and System 80 benchmark data

| Parameter                | Cost                   |
|--------------------------|------------------------|
| Natural U Mining/Milling | \$110/kgU              |
| Conversion               | \$10/kgU               |
| Enrichment               | \$110/SWU              |
| Fuel Fabrication         | \$350/kgU              |
| DU Conversion            | \$6/kgU                |
| Geologic Disposal        | \$1/MWeh               |
| Construction Cost*       | \$2366/kWe             |
| O&M Costs                | \$9.35/MWeh            |
| D&D Costs                | 21.55% of construction |

Fuel Cycle Costs based on AFCI Cost Basis  
Construction costs based on System 80

# Sample analysis from current version

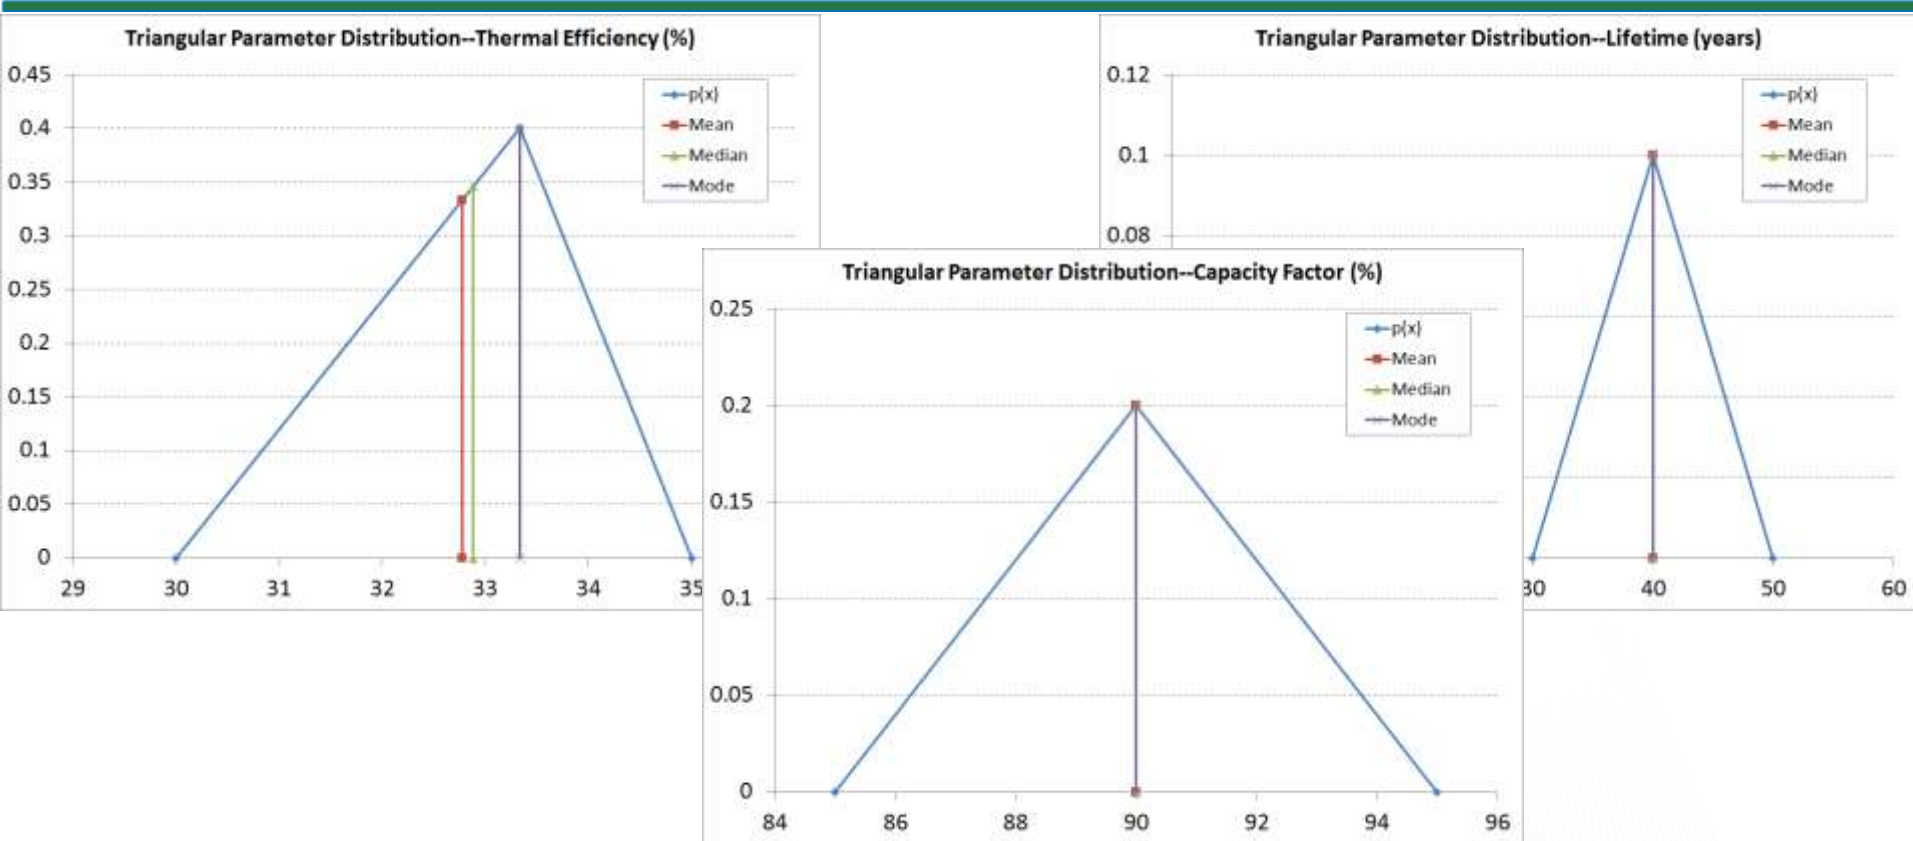

| Component            | Cost per MWeh |
|----------------------|---------------|
| Capital              | \$20.27       |
| O&M                  | \$9.35        |
| Fuel Cycle—Front End | \$5.28        |
| Fuel Cycle—Back End  | \$1.00        |
| D&D Sinking Fund     | \$0.52        |
| Total                | \$36.42       |

# These are operational parameters including uncertainty

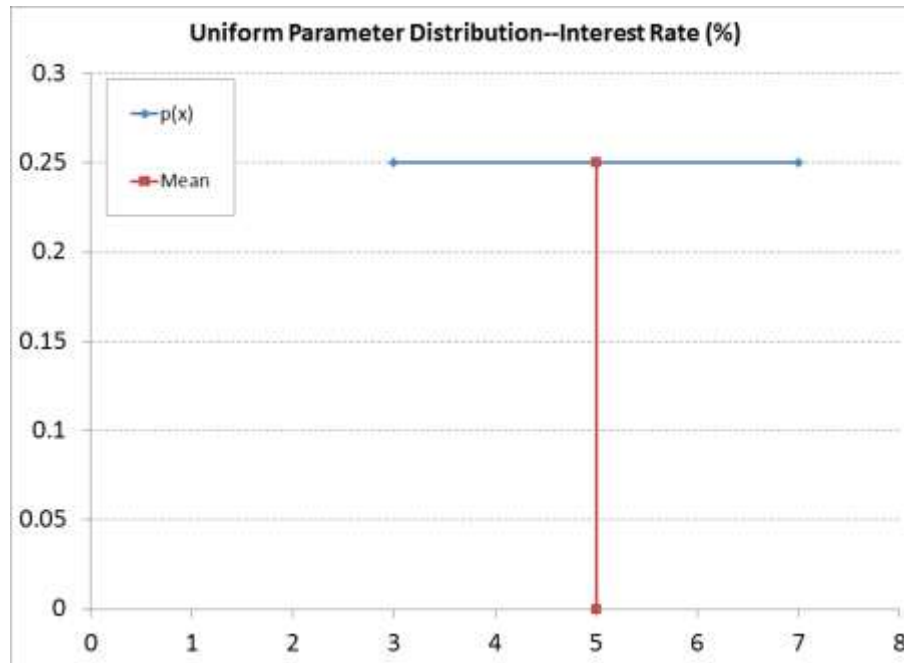

| Parameter          | Low             | Nominal  | High |
|--------------------|-----------------|----------|------|
| Reactor Type       | PWR             |          |      |
| Thermal Power      | 3900 MWt        |          |      |
| Power Density      | 38 MWt/MTU      |          |      |
| Fuel               | 3.78% LEU Oxide |          |      |
| Fuel Source        | Natural U       |          |      |
| Tails              | 0.21%           |          |      |
| Burnup             | 43.68 GWtd/MTU  |          |      |
| Thermal Efficiency | 30              | 33.33%   | 35   |
| Capacity Factor    | 85              | 90%      | 95   |
| Lifetime           | 30              | 40 years | 50   |
| Interest Rate      | 3               | 5%       | 7    |

# Efficiency, capacity factor, and lifetime assume triangular distributions

Triangular distributions show a “most likely” nominal value at the mode, but have definite end points

# Interest rates assume a uniform distribution

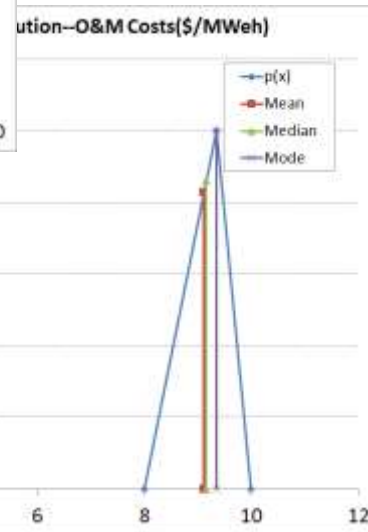

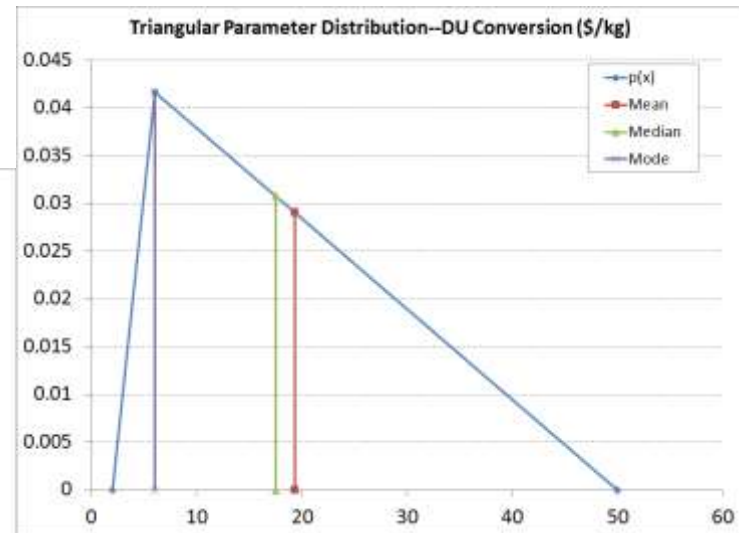

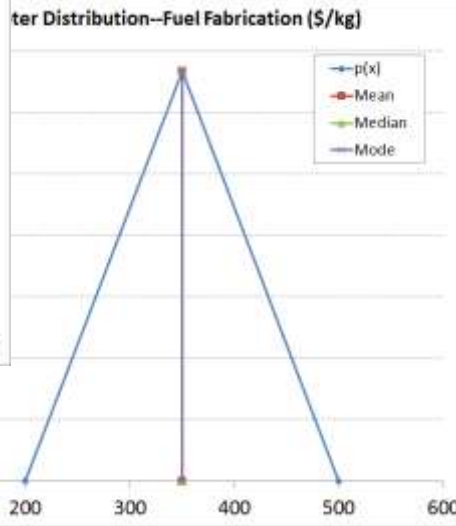

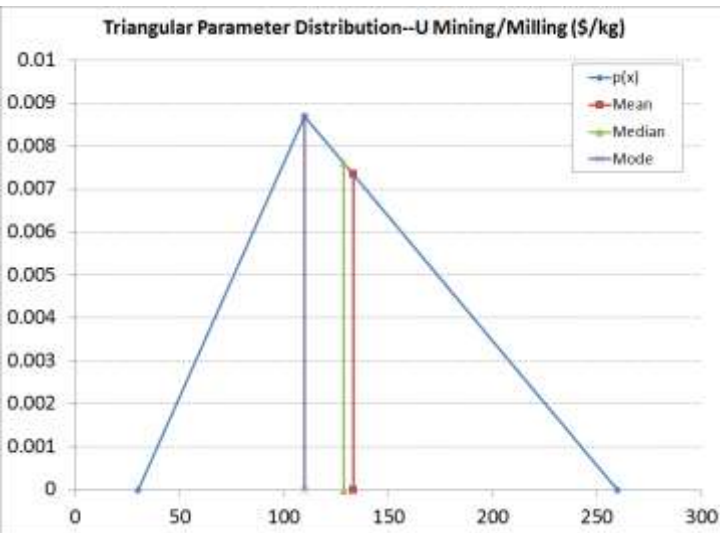

Uniform distributions have a range, without a “most likely” value (e.g., 5%)

# Fuel cycle and capital costs are assigned triangular distributions

| Parameter                | Low                    | Nominal     | High   |
|--------------------------|------------------------|-------------|--------|
| Geologic Disposal        | \$1/MWeh               |             |        |
| D&D Costs                | 21.55% of construction |             |        |
| Natural U Mining/Milling | \$30                   | \$110/kgU   | \$260  |
| Conversion               | \$5                    | \$10/kgU    | \$15   |
| Enrichment               | \$85                   | \$110/SWU   | \$135  |
| Fuel Fabrication         | \$200                  | \$350/kgU   | \$500  |
| DU Conversion            | \$2                    | \$6/kgU     | \$50   |
| Capital Cost             | \$2000                 | \$2366/kWe  | \$5000 |
| O&M Costs                | \$8                    | \$9.35/MWeh | \$10   |

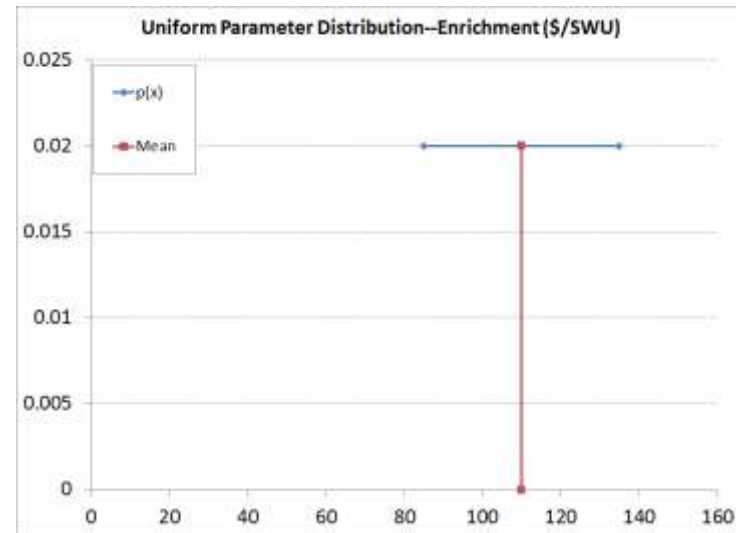

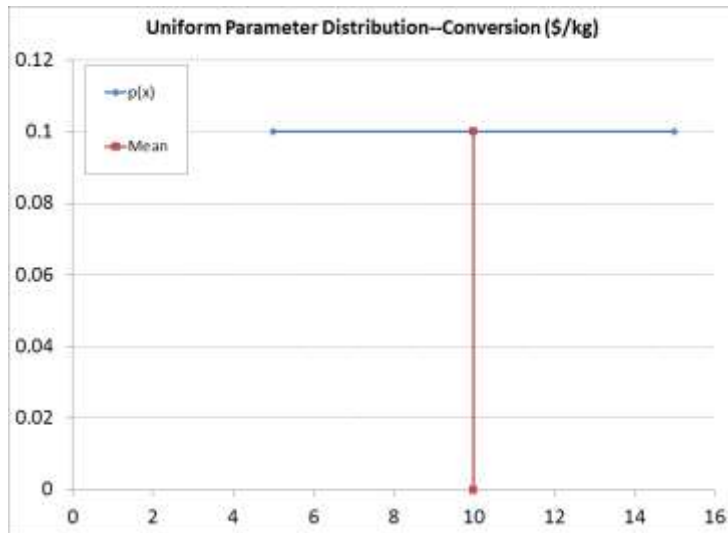

# Most cost parameters are assumed to follow triangular distributions

These have a “most likely” value

# Conversion and enrichment follow a uniform distribution

# Given the input parameters, the capital cost is represented by a right-skewed triangular distribution

# Capital cost drives ~74% of the total cost uncertainty, followed by interest during Operations at 22%

| Parameter                         | Variance (\$/MWeh) <sup>2</sup>        | Contribution to Total Variance |
|-----------------------------------|--|--------------------------------|
| Capital Cost                      | 34.49                                  | 73.80%                         |
| Interest Rate During Operation    | 10.29                                  | 22.00%                         |
| Mining/Milling                    | 0.94                                   | 2.00%                          |
| Interest Rate During Construction | 0.47                                   | 1.00%                          |
| Capacity Factor                   | 0.22                                   | 0.47%                          |
| O&M                               | 0.17                                   | 0.36%                          |
| All Others                        | 0.18                                   | 0.38%                          |
| Total                             | 46.76 → \$6.84/MWeh standard deviation |                                |

# The uncertainty distribution can account for extreme values while centralizing the most likely values

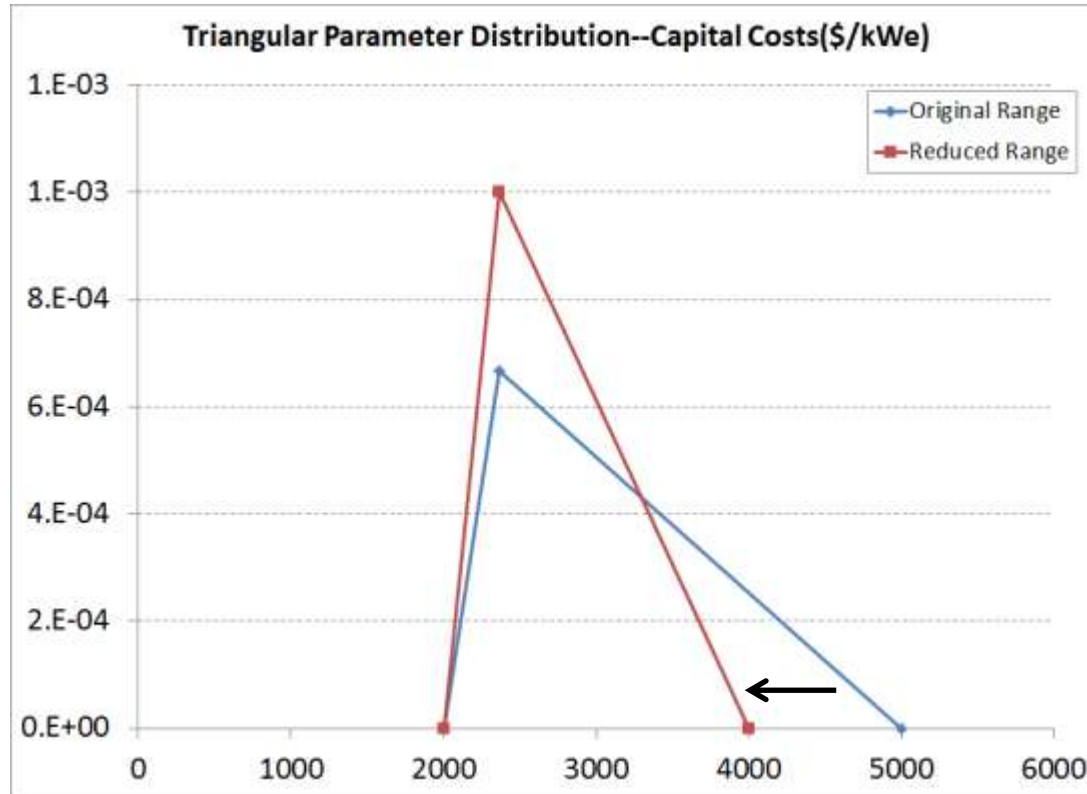

---

- Capital costs have some small probability of having both low-end and high-end values.
- The central estimate reflects the most likely case.
- Peaking the estimate near the low-end can hedge the estimate against potential high-end costs.

# For example, the high-end of the capital cost range is reduced by \$1000/kWe

| Parameter                | Low                    | Nominal     | High          |
|--------------------------|------------------------|-------------|---------------|
| Natural U Mining/Milling | \$30                   | \$110/kgU   | \$260         |
| Conversion               | \$5                    | \$12/kgU    | \$15          |
| Enrichment               | \$85                   | \$100/SWU   | \$135         |
| Fuel Fabrication         | \$200                  | \$350/kgU   | \$500         |
| DU Conversion            | \$2                    | \$6/kgU     | \$50          |
| Geologic Disposal        | \$1/MWeh               |             |               |
| Capital Cost*            | \$2000                 | \$2366/kWe  | <b>\$4000</b> |
| O&M Costs                | \$8                    | \$9.35/MWeh | \$10          |
| D&D Costs                | 21.55% of construction |             |               |

# Reducing the high-range value of the Capital shifts the distribution to the left

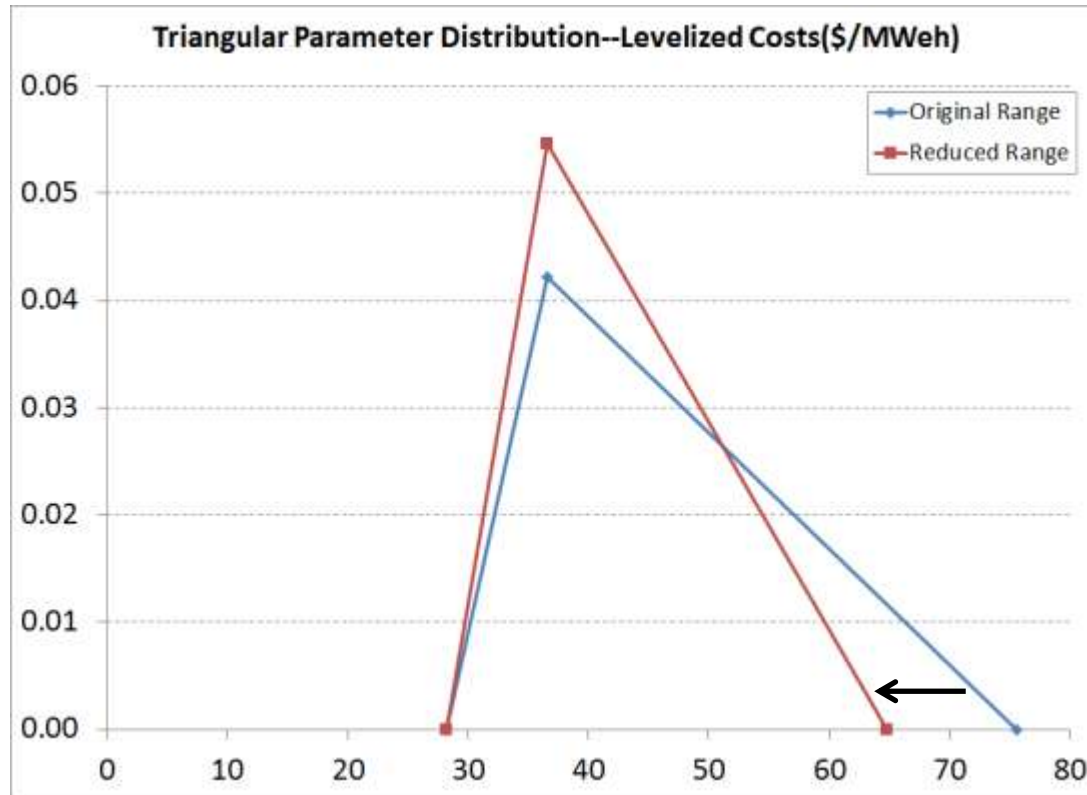

# Reducing the Capital cost results in a decrease from ~74% to ~54% in the overall estimate standard deviation

| Parameter                         | Variance (\$/MWeh) <sup>2</sup>               | Percent of Total Variance |
|-----------------------------------|---|---------------------------|
| Capital Cost                      | 14.6  | 54.3                      |
| Interest Rate During Operation    | 10.29   | 38.3                      |
| Mining/Milling                    | 0.94  | 3.5                       |
| Interest Rate During Construction | 0.47  | 1.8                       |
| Capacity Factor                   | 0.22  | 0.8                       |
| O&M                               | 0.17  | 0.63                      |
| All Others                        | 0.18  | 0.67                      |
| Total                             | 26.87 → \$5.18/MWeh standard deviation (~14%) |                           |

# The overall cost distribution (LUEC) correlates with the shift of capital cost

# Uncertainty analysis provides additional perspectives on the costs and potential risk of the investment

---

- Extending the end points of key cost parameters provides a means to account for contingency, but results in higher cost uncertainty
- Operational and commodity uncertainties are better understood and may be contained through best practices and supply chain efficiency
- Interest rate uncertainties have non-linear (compounding) effects but may be controlled by sovereign body policies (e.g., loan guarantees)

# Conclusions

---

- The GIF Economic Modeling Working Group developed and continues to enhance G4ECONS
- The revised version of G4ECONS includes uncertainty analysis to allow analysts to understand what drives the overall cost
- However it is necessary to be mindful of how the uncertainty is quantified!
